In chemistry, the linear molecular geometry describes the geometry around a central atom bonded to two other atoms (or ligands) placed at a bond-angle of 180° . Linear organic molecules, such as acetylene ($\text{HC}\equiv\text{CH}$), are often described by invoking sp orbital hybridization for their carbon centers.. According to the VSEPR model, linear geometry occurs at central atoms with two bonded atoms and ...

Valence shell electron pair repulsion (VSEPR) theory is a model used in chemistry to predict the geometry of individual molecules from the number of electron pairs surrounding their central atoms. It is also named the Gillespie-Nyholm theory after its two main developers, Ronald Gillespie and Ronald Nyholm. The acronym "VSEPR" is pronounced either "ves-pur": 410 or "vuh-seh-per".

A random number is a number chosen as if by chance from some specified distribution such that selection of a large set of these numbers reproduces the underlying distribution. Almost always, such numbers are also required to be independent, so that there are no correlations between successive numbers. Computer-generated random numbers are sometimes called pseudorandom numbers, while the term ...

Probably the most famous of the organometallic compounds is the exceedingly stable orange ferrocene, $[\text{Fe}(\text{C}_5\text{H}_5)_2]$. Its discovery in 1951 triggered an explosion in coordination chemistry, and the subsequent preparation of thousands of new organometallic compounds. Ferrocene consists of two planar, five-membered rings sandwiching an iron atom between them.

Laplace Transform. The Laplace transform is an integral transform perhaps second only to the Fourier transform in its utility in solving physical problems. The Laplace transform is particularly useful in solving linear ordinary differential equations such as those arising in the analysis of electronic circuits.. The (unilateral) Laplace transform (not to be confused with the Lie derivative ...
